

Clinical Note

Patient Name: Ahmed Ansari

MRN: SCB-16197

Date: 2026-05-15 16:10

Chief Complaint

Patient reports two days of abdominal pain, despite taking prescribed medication, with no improvement in symptoms.

History Of Present Illness

Patient has a history of mild hypertension, borderline type 2 diabetes risk, and mild lifestyle-related fatigue. Previous visits showed improvement in fatigue and chest discomfort, with controlled blood pressure and improved glucose regulation. Current complaint of abdominal pain is a new finding.

Assessment

New onset of abdominal pain, possible gastrointestinal side effects of current medication, or other underlying conditions. Comparison with previous reports shows overall clinical improvement in hypertension and glucose regulation, but current abdominal pain warrants further investigation.

Plan

Order abdominal ultrasound and complete blood count to investigate cause of abdominal pain. Review current medication for potential gastrointestinal side effects and consider alternative options. Continue to monitor blood pressure and glucose levels, with follow-up appointment in two weeks to reassess symptoms and adjust plan as needed.
